

Simulating Sampling Distributions and Confidence Intervals

Paul M. Magwene

Population of interest

Distribution of Heights in the Population of Interest

A random sample of size 25

Distribution of heights in the underlying population (grey) and for a single sample of size 25 (blue). The true population mean is shown as a solid line, the sample mean is shown as a dashed line

A second random sample of size 25

Distribution of heights in the underlying population (grey) and for a single sample of size 25 (blue). The true population mean is shown as a solid line, the sample mean is shown as a dashed line

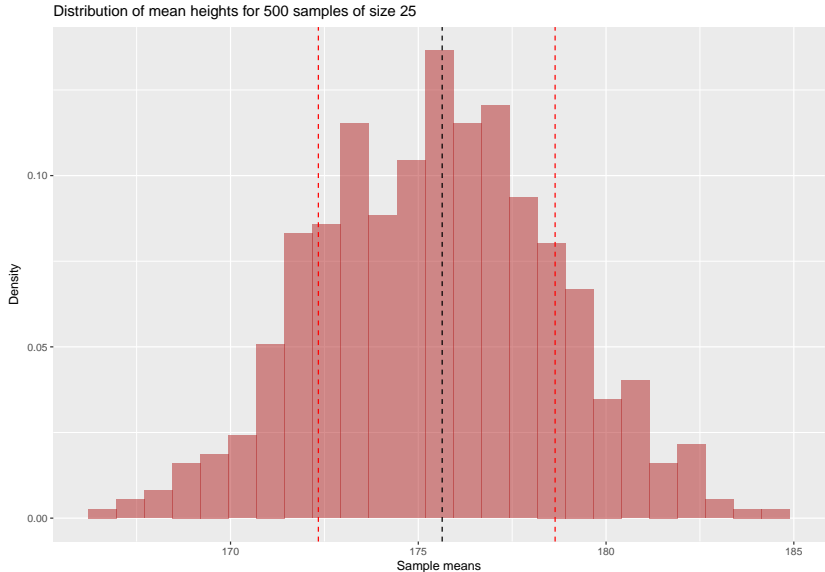

A third random sample of size 25

Distribution of heights in the underlying population (grey) and for a single sample of size 25 (blue). The true population mean is shown as a solid line, the sample mean is shown as a dashed line

Sampling distribution of the mean: Distribution of sample means across many random samples

Comparing the population distribution to the sampling distribution of the mean

Comparison of the population distribution of heights and the sampling distribution of mean heights for samples of size 25

Sampling Distributions and Standard Errors

Sampling Distributions

The **sampling distribution of a statistic of interest** is the probability distribution of a given statistic for samples of a given size.

Standard Errors

The **standard error of a statistic of interest** is the standard deviation of the sampling distribution for the given statistic

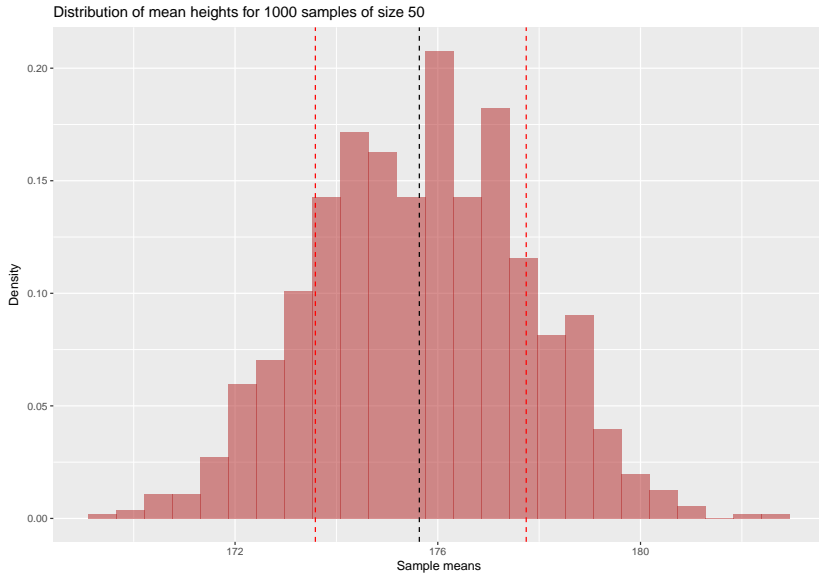

Uncertainty

Together, the sampling distribution and associated standard error for a given statistic are key measures of the uncertainty in statistical estimates

Point estimates of the mean for random samples of size 50

Sampling distribution of the mean

95% Confidence intervals for the mean for random samples of size 50

Interpreting confidence intervals

From NIST page on confidence intervals:

*As a technical note, a 95 % confidence interval does not mean that there is a 95 % probability that the interval contains the true mean. The interval computed from a given sample either contains the true mean or it does not. Instead, **the level of confidence is associated with the method of calculating the interval** ... That is, for a 95% confidence interval, if many samples are collected and the confidence interval computed, in the long run about 95% of these intervals would contain the true mean.*
